Retirement and depression

(Health and retirement study)

Dataset

selected

Health and Retirement Study - a survey of **Americans** (mostly **50+ years old**) about their health and employment/retirement status

A **complete** dataset is taken from the official website and data from **2002-2018** is

156227 records

28893 people

59% of women

41% of men

30+ sections

Relevance

The share of pensioners is **growing**

According to the data:

81.2% of pensioners are **not employed**

31% of retirees live **without a partner**

How does living with a partner in retirement affect depression levels?

Metric

Simplified CES-D **scale***

Loss of interest in familiar things
Constant fatigue
Trouble sleeping. Depressed.

Concentration problems
Loss/growth of appetite
Self-criticism

*developed by CES - Center for Epidemiologic Studies

Age distribution

Income distribution households

Distribution of non-zero CES-D scores

Zeros in CES-D are **80% of the** records

**Median retirement
age:**

62 years old

There are lifestyle changes in retirement:

↑ Free time ↓

Income

↓ Social contacts

Cohabitation status: 69% live with a partner 31% do not have a partner

Discarded:

All parameters CES-D - nan (30% of records)

CES-D score > 3 (7% of records)

CES-D score по возрастным группам

Возрастная группа (< n - группе меньше n лет, n+ - группе не меньше n лет)

Metric

In testing the hypothesis, the **CES-D score mean change** comparison method was used in different groups of respondents

Hypothesis 1

Those living **without a partner** are more susceptible to depression in **retirement**, compared to those who live **with a partner**

Mechanism

People continue to **socialize only with their closest loved ones**, retirees without partners **live alone**, leading to **increased levels of depression**

Null hypothesis

The change in the level of depression is **independent of whether the**
respondent lives **with** or without a **partner**

α significance level = 0.05

Hypothesis testing

Mean change in CES-D score:

Living **with** a retired **couple**

+3.65% CES-D

Sampling = 2194

Lives **without** a retired **couple**

+14.68% CES-D

Sample = 1042

Permutation test of the mean: p-
value = 0.0002

Hypothesis 2

When living with a partner, other social contacts have no effect on levels of depression

Mechanism

People spend much more time with their spouse, the spouse dominates life much more than other people, especially at older ages

Hypothesis testing

Question: *How often do you get together with people just to chat or for a social visit? (18923 lines)*

Deleted: less frequently than once a month (838 rows), points with <100 values (12 observations

deleted) Grouping by response:

1. Almost every day (12%)
2. Once a week or two (64%)
3. Once a month (24%)

Null hypothesis

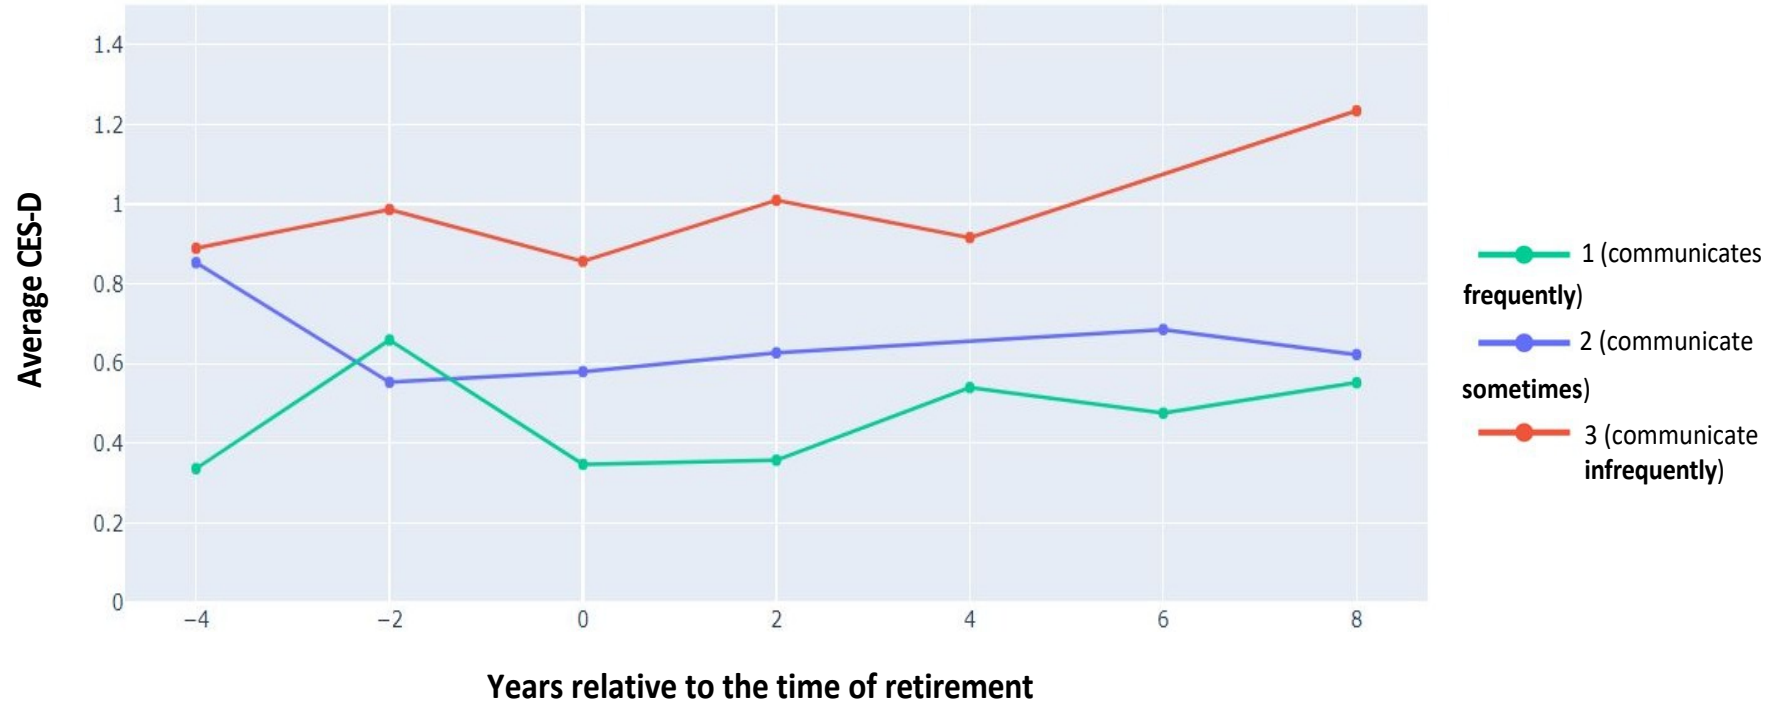

Amount of social contact **has an effect** when calculating depression levels with a partner

α significance level = 0.05

Living with a retired partner

Living without a partner in retirement

Hypothesis testing

Let's do a **permutation test**

For each group, we compare the mean CES-D scores standing next to each other in time

Permutation test of the mean: p-value = 0.0126

Conclusions

The first hypothesis is confirmed: people living **without a partner are** more likely to be **depressed in** retirement compared to those living **with a partner**

The second hypothesis was confirmed: when living **with a partner**, other social contacts **have a** weak effect on levels of **depression**

Call to action

! To develop the topic of family **psychology** for pensioners

! Adult "children" - **be more attentive to** parents so they are not **alone** with their spouse/self

! Pensioners should **not limit** their social contacts to their spouse alone

Research Perspectives

Improving accuracy: more clarifying questions on CES-D

Deepen: track all health as a whole

View by: regions, professions

Long-term dynamics: interview groups of people over 15-20 years
